

GRAPH DRILL SESSION

↳ satisfiability of Equality Equations

→ If $a == b$, it means a equals to b then b also equals to a . so we can say that a is connected to b with an undirected edge.

→ ~~If~~ $b == c$

implies $a == c$, \rightarrow TRUE

If given $a \neq c \rightarrow$ then we will ^{return} ~~range~~ = False.

Approach :- $O(V+E)$

1. Make a graph with the help of adjacency list.

2. In the adjacency list, if $a == b$ then a will have b and vice-versa.

3. Perform DFS to find connected components.

4. Iterate through the inequality equation to check for contradictions.

→ If two variables in an inequality are found in the same component, it's a logical contradiction.

If $d == f$, but the graph place them both in component 2, the conditions cannot be satisfied and result is false.

2. Fox and Two Dots

This problem asks to find if there is a cycle of four or more dots of the same color on a grid. The grid itself can be treated as a graph.

Approach: Cycle Detection in an Undirected graph

1. DFS Traversal: Iterate through each cell of the grid. If a cell hasn't been visited, start a DFS from it.
2. During the DFS from a cell (i, j) , only explore adjacent neighbouring cells that have the same color.
3. A cycle is detected when the traversal from the current node encounters a neighbour that has already been visited in the current DFS path and is not its immediate parent. This previously visited node is an ancestor.

4. To identify, use a map or visited array specific to the current traversal path.
5. Cycle must have at least 4. This can be verified by tracking the depth of each node in the DFS traversal. If a back edge is found to an ancestor, the length of cycle = difference in depths + 1. The distance must be ≥ 4 .
6. If a cycle meeting all conditions (same color, length ≥ 4) is found, return true. If the entire grid is traversed without finding such a cycle, return false.

3^o Maze

Goal : Convert exactly k empty cells into walls such that the remaining empty cells form a connected component.

Key Idea :-

- Treat the maze as a graph where:
 - Vertices = empty cells
 - Edges = adjacency b/w cells
- If we block a cell, it loses its neighbours.
- Need to ensure the remaining graph stays connected.

Observation :-

1. Leaf Nodes in DFS Traversal
 - leaf Node = empty cell that cannot move further in DFS (only 1 connection left).
 - If we want to block cells, start from leaf node first.
 - Remove them one by one until k blocks walls are placed.
2. Order of Removal
 - Always prioritize removal of leaf node with lowest degree (fewer connection)
 - After removing a leaf, its parent may become a new leaf → continue

Approach :-

- 1° Count total open cells s .
- 2° Required open cells after blocking $= s - k$
- 3° Start DFS/BFS from any empty cell.
- 4° Traverse until visiting $s - k$ cells.
- 5° Remaining unvisited empty cells \rightarrow mark as walls (X).

Multiple connected components

If maze has multiple disconnected open regions:

→ choose one connected component.

→ Maintain $s - k$ open cells inside it.

Exa: # . # .

. # . #

... . . .

Open cells = 6

If $k = 3 \rightarrow$ keep 3 cells connected block rest.
